

Development of an Outcomes-based edX MOOC using LaTeX

David Darmofal¹, Chad Lieberman²

¹Professor of Aeronautics & Astronautics

²Lord Foundation Post-doctoral Associate

Acknowledgments

- Dr. Alejandra Uranga, co-instructor of 16.101x
- Savithru Jayasinghe, graduate TA of 16.101x
- Undergraduate TAs of 16.101x
- MITx for financial and general support

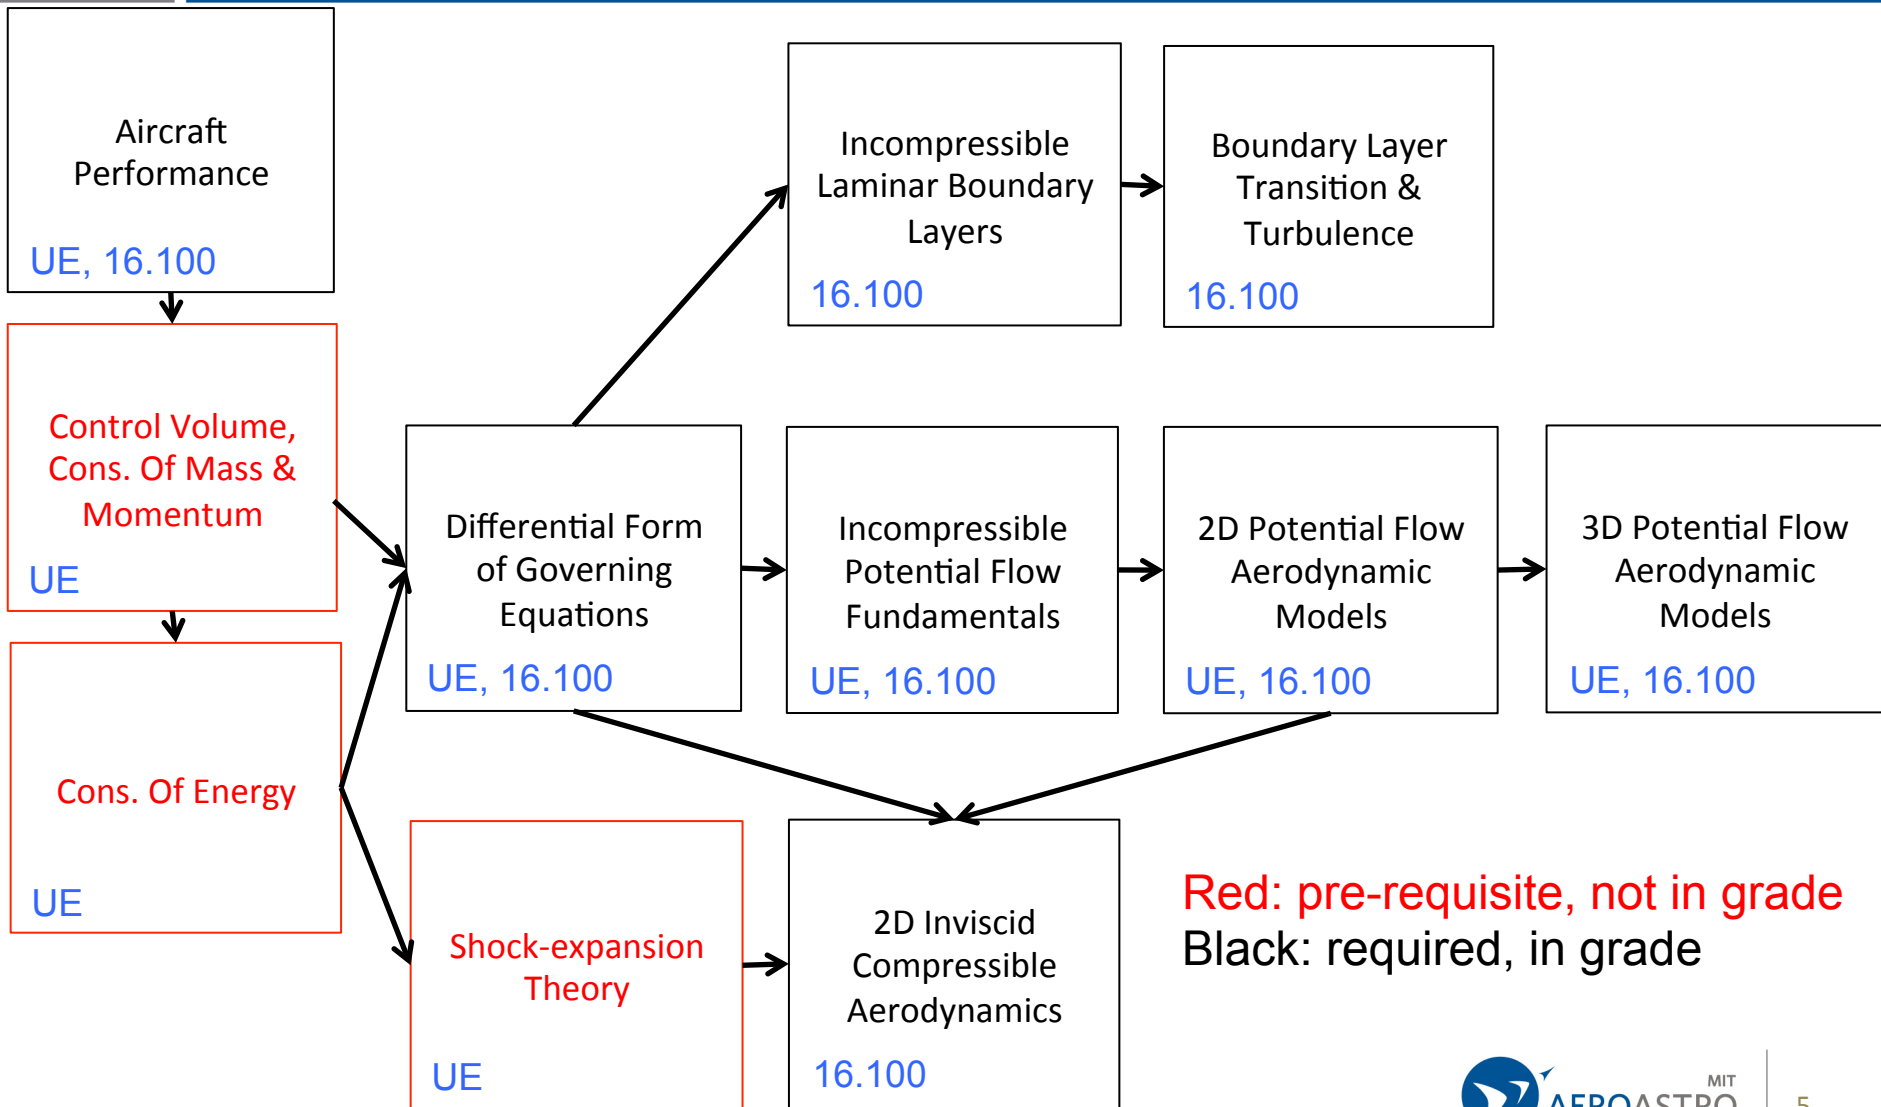

Outline

- Structure of 16.101x Introduction to Aerodynamics
- Outcomes-based MOOC
- LaTeX-driven edX MOOC development

Relationship to MIT subjects

- Undergraduate aerodynamics on campus taught in:
 - Sophomore core subject Unified Engineering (~12 units)
 - Junior/senior elective subject: 16.100 Aerodynamics (12 units)
- 16.101x:
 - Overlaps with Unified and 16.100
 - But without project-based learning
- Plan to utilize 16.101x material in Unified and 16.100

16.101x Modules

Red: pre-requisite, not in grade
Black: required, in grade

Structure of 16.101x Module

- Notes:
 - Embedded questions for checking understanding
 - Solution videos (tablet-based) provided
 - Occasional short (tablet-based) “lecture” videos
 - Homework problems:
 - More challenging than embedded questions
 - Solutions videos provided after due date.
 - Sample problems:
 - Same level as homework problems
 - Solution videos provided
 - Discussion forum
- | | |
|---------------------|-------|
| Embedded questions: | 5-10 |
| Homework problems: | 2-3 |
| Sample problems: | 2-3 |
| “Lecture” videos: | 2-4 |
| Videos per module: | 11-20 |
| Videos in total: | ~185 |

Conservation of Energy and Quasi-1D Flow

Entrance Survey

Differential Forms of Compressible Flow Equations

Fundamentals of Incompressible Potential Flows and Airfoils

RANGE

MO1.8

The range of an aircraft is the distance the aircraft can fly on a specific amount of fuel. In this section, our objectives are to understand how factors such as the weight of the aircraft, the amount of fuel, the drag, and the propulsive efficiency, influence an aircraft's range, and to learn how to estimate the range.

In our estimate, we will not directly consider the fuel used during the take-off and landing portions of a flight. We will only focus on the cruise range. Except for very short flights (an hour or less), most of the fuel is burned during the cruise section of the flight: for a typical commercial airliner in transcontinental flight, the fuel consumed during cruise represents around 90% of the total trip fuel. We will assume that an aircraft in cruise has constant speed (relative to the wind) of V_∞ and is flying level (not gaining altitude). This is commonly referred to as steady, level flight. Placing the freestream along the x -axis, and with gravity acting in the $-z$ direction, the forces acting on the aircraft are as shown in Figure 1.12.

Figure 1.12: An aircraft in steady level flight

Note: This screenshot will be shown in a live demo.

16.101x: Measurable outcome index

MO1.6 (a) Define the Mach number, (b) Define the Reynolds number, and (c) Define the angle of attack.

MO1.7 (a) Explain the concept of dynamic similarity, (b) Explain its importance in wind tunnel and scale-model testing, and (c) Determine conditions under which flows are dynamically similar.

MO1.8 (a) Derive the Breguet range equation, (b) Explain how the aerodynamic, propulsive, and structural performance impact the range of an aircraft using the Breguet range equation, and (c) Apply the Breguet range equation to estimate the range of an aircraft.

CONTROL VOLUME ANALYSIS OF MASS AND MOMENTUM CONSERVATION

MO2.1 Describe a continuum model for a fluid and utilize the Knudsen number to support the use of a continuum model for typical atmospheric vehicles.

MO2.2 Define the density, pressure, and velocity of a flow and utilize a field representation of these (and other) fluid states to describe their variation in space and time. Define the difference between a steady and unsteady flow.

MO2.3 Define pathlines and streamlines and describe their relationship for unsteady and steady flow.

RANGE ESTIMATE FOR A LARGE COMMERCIAL TRANSPORT (5.0/5.0 points)

MO1.4 MO1.8

Consider a commercial transport aircraft with the following characteristics:

- W_{initial} 400,000 kg
- W_{fuel} 175,000 kg
- η_o 0.32
- L/D 17
- Q_R 42 MJ/kg
- g 9.81 m/sec²

Note that we have given the weights W_{initial} and W_{fuel} in kilograms, which is actually a unit of mass. This is fairly common usage when giving weights in metric units, that is weights are often given as mass. To find the weight, we need to multiply the given masses by gravity. So, in reality, $W_{\text{initial}} = 3,924,000$ N and $W_{\text{fuel}} = 1,716,750$ N. However, for the Breguet range equation, we only use the ratio of weights which would be the same as the ratio of masses, that is $W_{\text{initial}}/W_{\text{final}} = m_{\text{initial}}/m_{\text{final}}$. But, be extra careful, because if you actually were to calculate the lift, or the lift coefficient, the weight needs to be in units of force (i.e. Newtons in metric)!

Estimate the range (during cruise portion of flight) for this aircraft. Please use kilometers and provide an answer that has three significant digits of precision.

Note: This screenshot will be shown in a live demo.

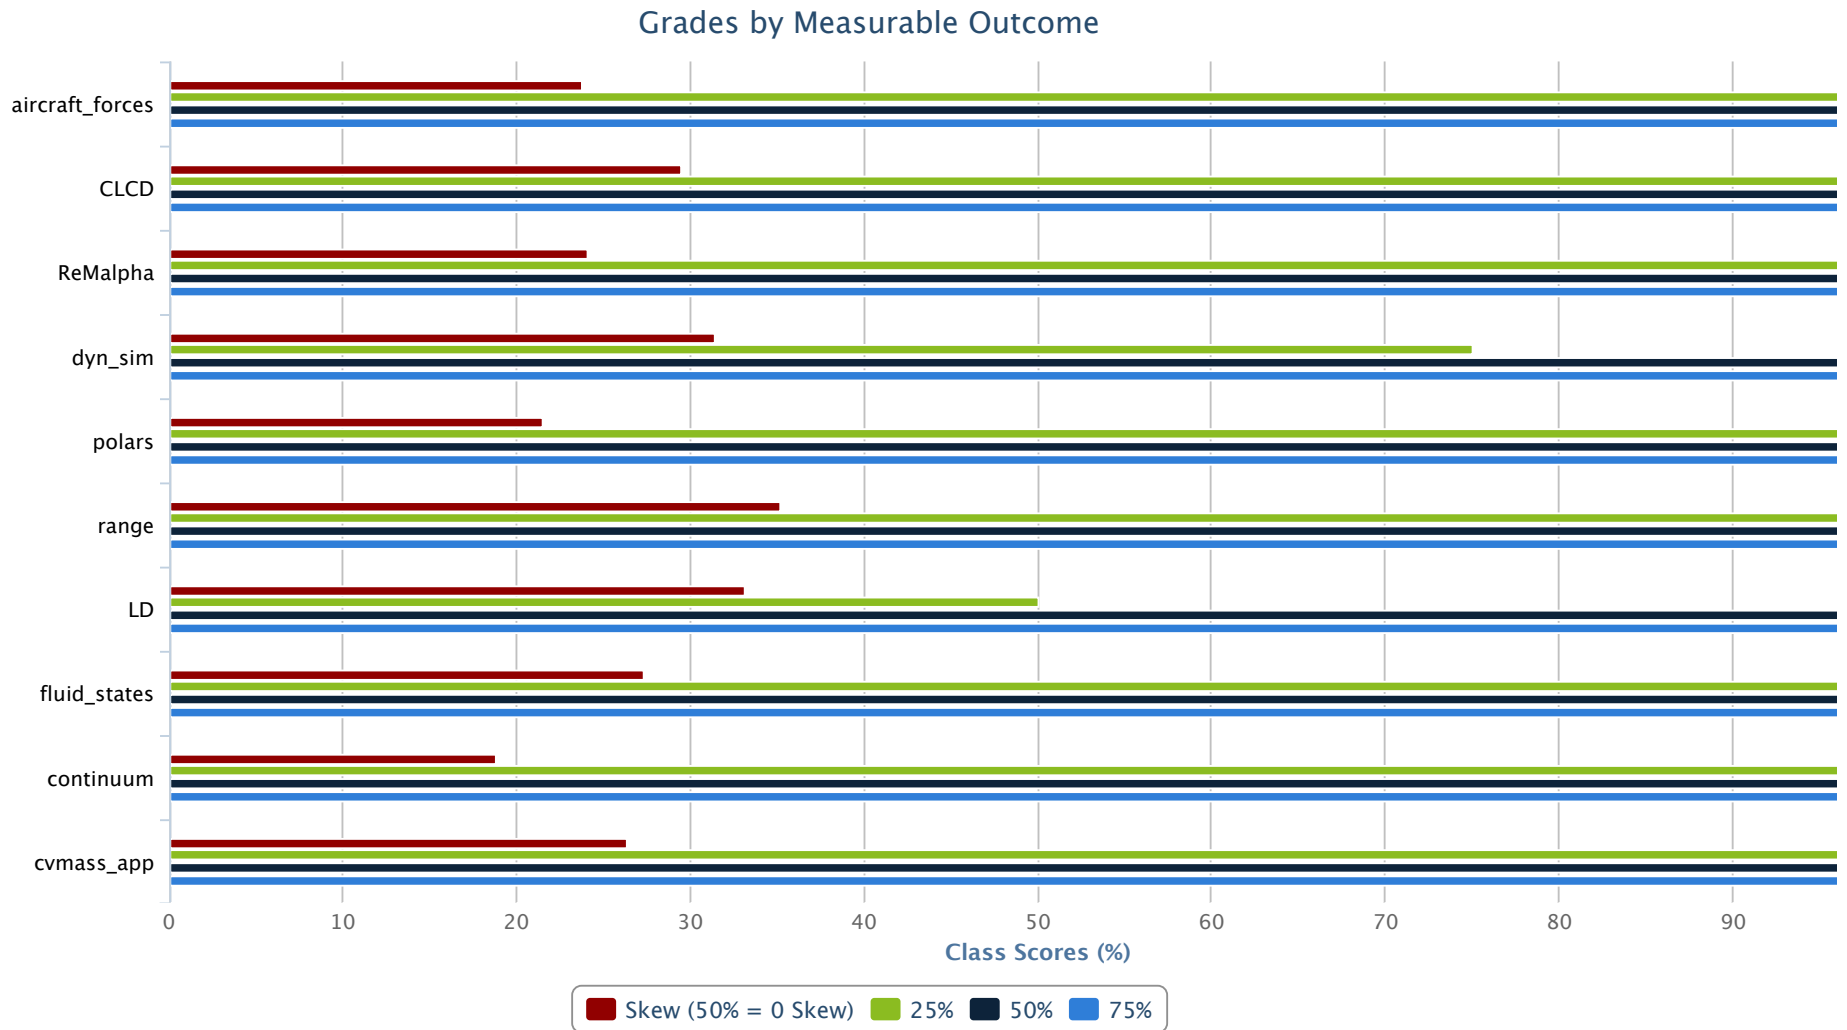

Demo of 16.101x Module Content

- Give a live demo of 16.101x module content
- Show notes, embedded questions, solution videos, “lecture videos”, homework problems, ...
- Initially do not point out/discuss MOs

Demo of 16.101x M.O.

- Give a live demo of M.O. capability
- Start by showing an Overview section of a module with the M.O. list
- Then show how all content (notes and problems) are labeled by M.O.s (and show hover technique)
- Then click on M.O. to reveal M.O. index

Class performance on all outcomes

On-going work with OEIT to develop M.O. reporting tool

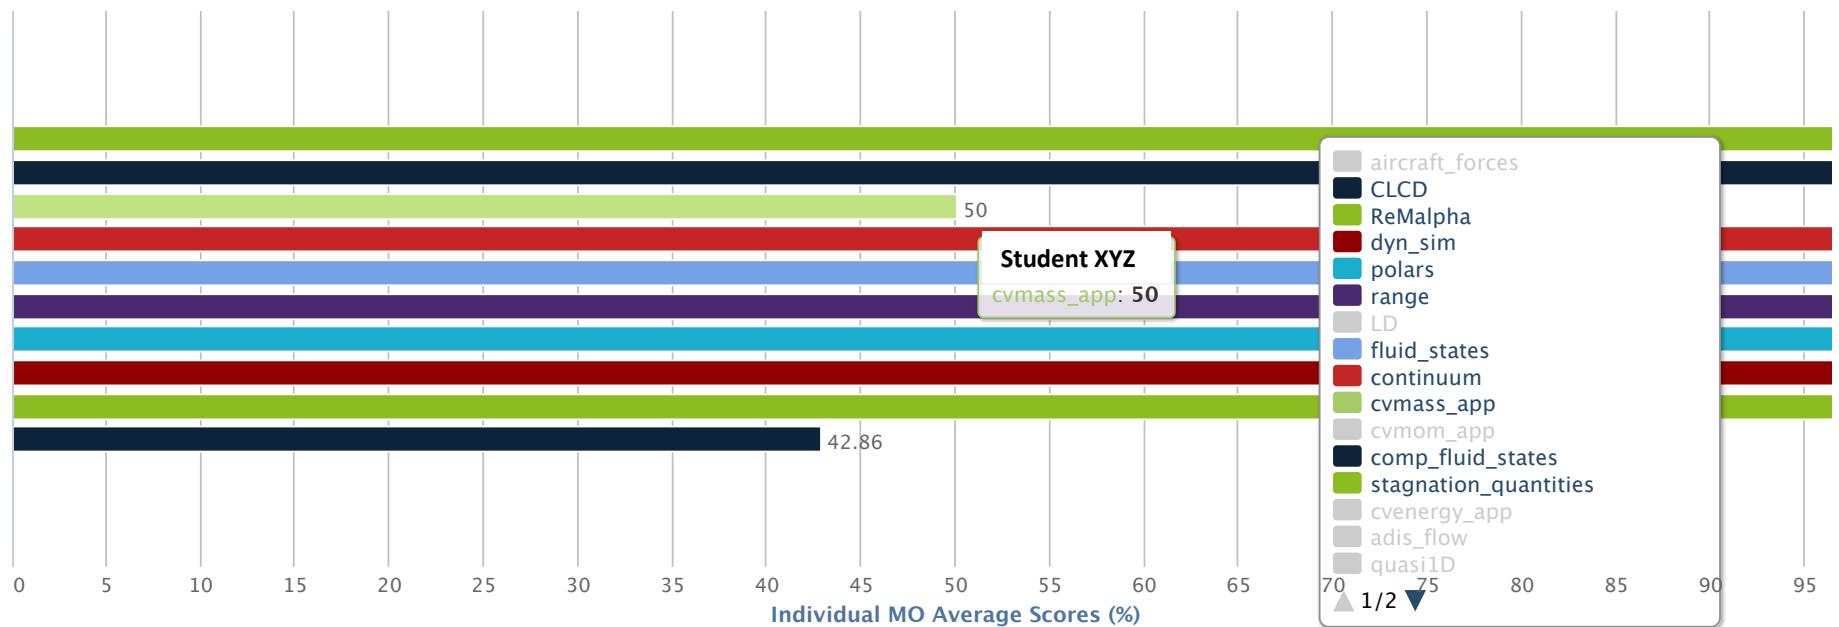

Class performance on a single outcome

MO2.6: Apply the integral form of mass conservation to typical problems in aerospace engineering.

On-going work with OEIT to develop M.O. reporting tool

Individual student performance on outcomes

On-going work with OEIT to develop M.O. reporting tool

LaTeX-based development process

- LaTeX is a document preparation system and markup language
- Traditionally LaTeX is used in academia for preparing books, journal articles, and lecture notes
- From text source, a PDF is generated according to specified styles
- Some advantages include ease of re-use; section, equation, and figure referencing; hyperlinks; etc.

L^AT_EX

LaTeX-based development process

- LaTeX2edX is a python-based software utility that produces edXxml from LaTeX source
- Course content is developed in a convenient and well-known form (i.e., LaTeX)
- Content developers are insulated from the complexity/nuance of html/xml in the edX platform
- Easy to re-use content and generate PDFs for offline development and viewing
- Conversion process is automatic permitting generation of MO Index, MO labelling, figure and equation pop-up references

The screenshot shows a web browser window with the URL https://courses.edx.org/courses/MITx/16.101x/2013_SOND/courseware/Aircraft_Performance/Overview2/. The page content includes a navigation menu with 'Overview of 16101x' and 'Office Hour Videos'. Under 'Aircraft Performance', there are three items: 'Overview' (due Oct 03, 2013 at 21:00 UTC), 'Forces on an Aircraft' (Aircraft Performance Embedded Questions Sequence 1 due Oct 03, 2013 at 21:00 UTC), and 'Non-dimensional Parameters and Dynamic Similarity' (Aircraft Performance Embedded). The main content area shows '1.1.1 MEASURABLE OUTCOMES' with a description of the module's objectives and a note that students successfully completing the module will be able to:

- MO1.1: (a) Define the gravitational, propulsive, and aerodynamic forces that act on an airplane, and (b) Relate the motion of an aircraft (i.e. its acceleration) to these forces.

- MO1.5: (a) Explain the relationship between the CL-alpha curve and drag polar, and (b) Utilize CL-alpha curves and drag polars to analyze the aerodynamic performance of an aircraft.
- MO1.6: (a) Define the Mach number, (b) Define the Reynolds number, and (c) Define the angle of attack.

\relmo{\ref{mo:CLCD}, \ref{mo:ReMalpha}, \ref{mo:dyn_sim}}
```

One of the important reasons for using the lift and drag coefficients arises in wind tunnel testing, or more generally experimental testing of a scaled model of an aircraft. For example, suppose we have a model in the wind tunnel that is a 1/50th scale version of the actual aircraft, meaning that the length dimensions of the model are 1/50 the length dimensions of the actual aircraft.

The key question in this scaled testing is: how is the flow around the scaled model of an aircraft related to the flow around the full-scale aircraft? Or, more specifically, how is the lift and drag acting on the scaled model of an aircraft related to the lift and drag acting on the full-scale aircraft?

While almost certainly the actual lift and drag are not equal between the scale and full-scale aircraft, the intent of this type of scale testing is that the lift and drag coefficients will be equal. However, this equality of the lift and drag coefficients only occurs under certain conditions and the basic concept at work is called `\textit{dynamic similarity}`.

The following video describes the concept of dynamic similarity.

```
\edXinlinevideo{sielcT...}

```

The screenshot shows a web browser window displaying a course page. The page title is "1.3.5 INTRODUCTION TO DYNAMIC SIMILARITY". Below the title are three navigation buttons: "MO1.4", "MO1.6", and "MO1.7". The page content includes a sidebar with "Office Hour Videos" and "Aircraft Performance" sections. The main content area contains text about dynamic similarity and a video player. The video player shows a grid pattern, likely a video frame.

This inset box highlights the title and navigation buttons from the screenshot above. The title is "1.3.5 INTRODUCTION TO DYNAMIC SIMILARITY" and the buttons are "MO1.4", "MO1.6", and "MO1.7".

Future Plans

- Utilize 16.101x resources for on-campus subjects
- Improve edX support of outcome-based MOOCs
- Encourage LaTeX-driven development of edX classes
